Data set up

٧

6

As before, you will need to load the data from he github resource

```
library(GISTools)
library(spgwr)
library(repmis)
source_data("http://github.com/lexcomber/LexTrainingR/blob/master/SpatialAccuracy.RData?raw=True")
## [1] "lib"
              "data"
And have a look at the what you have
ls()
## [1] "data" "lib"
head(data.frame(data))
##

Putting it all together with Loops and Functions

So far we have examined overall accuracy and per class User and Producer accuracies individually, showing the original aspatial or global measure, and then a summary of the distribution of the related geographically weighted values. The accuracy surfaces have then been mapped using the level.plot function in the GISTools package.

The code above has been developed and described step by step to walk you through the process.

It might be useful to develop functions to automate some of these operations. And then perhaps to combine some of these functions so that for any given class, a number of accuracy measures are returned. The code in this section starts to do this.

Overall Accuracy

Remember that Overall Accuracy is calculated from the sum of the diagonals in the accuracy / confusion / error / validation matrix that compares *Predicted* against *Observed* classes, divided by the total number of data points.

```
res <- vector(length = dim(data)[1])
for (i in 1: dim(data)[1]) {
   if (data$Boolean_RS[i] == data$Boolean_FS[i]) {
      res[i] <- 1
   }}</pre>
```

This can be calculated from the data directly:

```
cat("overall accuracy:", sum(res)/length(res))
```

overall accuracy: 0.6

Or from a logistic regression and a the alogit function:

```
mod.ov <- glm(res~1,family= binomial)
mod.coefs <- mod.ov$coefficients
mod.coefs[2] <-sum(mod.coefs)
alogit <- function(x){exp(x)/(1+exp(x))}
mod.ov <- alogit(mod.coefs[2])
cat("overall accuracy:", mod.ov)</pre>
```

overall accuracy: 0.6

And if a SpatialPointsDataFrame object is created this can be used in a GW approach with the ggwr function. First some variables and parameters need to be set:

```
bw = 0.15
grid <- SpatialPoints(expand.grid(x=seq(295000,363000,by=1000),
    y=seq(3610000,3646000,by=1000)))
res.spdf <- SpatialPointsDataFrame(coords = data[,2:3],
    data = data.frame(res))</pre>
```

Then the GW model can be constructed:

```
gwr.mod <- ggwr(res~1, data = res.spdf, adapt = bw,
  fit.points = grid, family= binomial)
gwr.ov <- alogit(data.frame(gwr.mod$SDF)[,2])</pre>
```

And the variation in the distribution of Overall Accuracy values examined:

```
## Min. 1st Qu. Median Mean 3rd Qu. Max.
## 0.5717 0.5962 0.6057 0.6053 0.6104 0.6446
```

Create a Function

A function to do all of this can be assembled from the above code snippets.

First of all it would be useful to create a SpatialPointsDataFrame of the all of the original data - this is the kind of dataset that you might bring as shapefile to this kind of analysis:

```
spdf <- SpatialPointsDataFrame(coords = data[,2:3], data = data.frame(data))
head(data.frame(spdf))</pre>
```

```

                                    TRUE
```

Then define a function that takes this spdf as input and returns a SpatialGridDataFrame with the results of the geographically weighted analysis:

```
gw.accuracy <- function(spdf, Field.class = "Boolean_FS",
    RS.class = "Boolean_RS", bw = 0.15, grid=grid, family= binomial){
# compare predicted and observed (classified and field)
res <- as.vector(spdf@data[RS.class] == spdf@data[Field.class]) * 1
# notice how the line of code above replaces the specification of</pre>
```

```
# the res vector, the for loop etc
# Commented Out: A-spatial overall accuracy
# cat("Overall accuracy:", sum(res)/length(res), "\n")
# GW approach
alogit <- function(x){exp(x)/(1+exp(x))}
gwr.mod <- ggwr(res~1, data = spdf, adapt = bw,
    fit.points = grid, family= binomial)
gwr.ov <- alogit(data.frame(gwr.mod$SDF)[,2])
# Commented Out: Summary of the GW variation
# cat("GW overall accuracy:", summary(gwr.ov))
# create SpatialPixelsDF to return from the function
gw.spdf <-SpatialPixelsDataFrame(gwr.mod$SDF, data.frame(gwr.ov))
return(gw.spdf)
}</pre>
```

And then this function can be run:

```
tmp <- gw.accuracy(spdf, Field.class = "Boolean_FS",
    RS.class = "Boolean_RS", bw = 0.15, grid, family= binomial)</pre>
```

And the results in tmp can be evaluated:

```
summary(tmp)
```

```
## Object of class SpatialPixelsDataFrame
## Coordinates:
        min
## x 294500 363500
## y 3609500 3646500
## Is projected: NA
## proj4string : [NA]
## Number of points: 2553
## Grid attributes:
## cellcentre.offset cellsize cells.dim
## x
              295000
                          1000
                                      37
## y
              3610000
                          1000
## Data attributes:
##
       gwr.ov
## Min. :0.5717
## 1st Qu.:0.5962
## Median :0.6057
## Mean :0.6053
## 3rd Qu.:0.6104
## Max. :0.6446
```

Create a Mapping Function

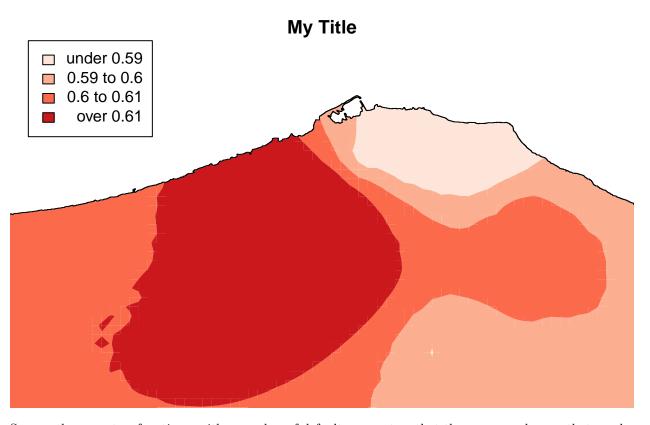

And the SpatialPixelsDataFrame can be mapped by defining a mapping function:

```
gw.mapping <- function(grd, index = 1, cols=brewer.pal(4,'Reds'),
bounding.poly = lib, x = 297000, y = 3650000, tit = "My Title") {</pre>
```

```
z = data.frame(grd)[, index]
zz = z[!is.na(z)]
shades <- auto.shading(zz, cols = cols)
level.plot(grd, index = index, shades = shades)
masker = poly.outer(grd, bounding.poly, extend = 100)
add.masking(masker)
plot(bounding.poly, add = T)
choro.legend(x, y,shades)
title(tit)}</pre>
```

Hint the locator function can be used to identify the x and y coordinates for the choro.legend function.

```
par(mar = c(0,0,1,0))
gw.mapping(tmp)
```

So now there are two functions, with a number of default parameters that the user can change, that can be called to calculate and then map overall accuracy:

```
tmp <- gw.accuracy(spdf)
gw.mapping(tmp)</pre>
```

User and Producer Accuracies

So far we have just mapped User and Producer accuracies for the class of Grazing Land. This class was chosen to exemplify the GW methods because it *does* exhibit spatial variation in these accuracies. But this might be the case for all classes. So, in this section we will first construct a function to compute the the GW

User and Producer accuracies for all classes. Then we will examine the spatial variation and select per-class accuracies to map.

The stages in this are:

- 1. For each class, construct a variable pair of remote sensing (Predcited) class and field (Observed) class:
- 2. Compute the GW User accuracy
- 3. Compute the GW Producer accuracy
- 4. Add the results to a data frame
- 5. Create a SpatialPixelsDataFrame
- 6. Evaluate the variation of the GW accuracy measures

```
# define the classes
class.list <- unique(data$Boolean RS)[order(unique(data$Boolean RS))]</pre>
# pass this into a loop
for (i in 1:length(class.list) ){
  class <- class.list[i]</pre>
  # 1. Construct the variable pair
  # RS indicates the class
  rs.class <- (data$Boolean RS == class) * 1
  # FS indicates the class
  fs.class <- (data$Boolean_FS == class) * 1</pre>
  # join together
  fsrs <- data.frame(cbind(fs.class,rs.class))</pre>
  # convert to SPDF
  fsrs.spdf <- SpatialPointsDataFrame(coords = data[,2:3],</pre>
    data = data.frame(fsrs))
  # 2. GW User accuracy
  # define a bandwidth
  bw = 0.15
  # construct GW model
  gwr.mod <- ggwr(fs.class~rs.class, data = fsrs.spdf,</pre>
    adapt = bw,fit.points=grid, family= binomial)
  coefs <- data.frame(gwr.mod$SDF)[,2:3]</pre>
  coefs[,2] <- rowSums(coefs)</pre>
  alogit <- function(x)\{\exp(x)/(1+\exp(x))\}
  gwr.user <- alogit(coefs[,2])</pre>
  # 3. GW Producer accuracy
  gwr.mod <- ggwr(rs.class~fs.class, data = fsrs.spdf,</pre>
    adapt = bw,fit.points=grid, family= binomial)
  coefs <- data.frame(gwr.mod$SDF)[,2:3]</pre>
  coefs[,2] <- rowSums(coefs)</pre>
  gwr.producer <- alogit(coefs[,2])</pre>
  # 4. Add these to the data frame
  # define some variable names
  tit.user <- sprintf("%s-User", class)</pre>
  tit.producer <- sprintf("%s-Producer", class)</pre>
  df <- data.frame(gwr.user, gwr.producer)</pre>
  # name the df
  names(df) <- c(tit.user, tit.producer)</pre>
  # and combine
  if(i ==1) df.res \leftarrow df
  if(i > 1) df.res <- data.frame(df.res, df)</pre>
}
```

The spatial variation in the coefficients is indicated by the distribution of User accuracy values:

```
summary(df.res)
```

```
G.User
##

```

And these can used to construct a SpatialPixelsDataFrame object:

```
gw.all.spdf <-SpatialPixelsDataFrame(gwr.mod$SDF, data.frame(df.res))</pre>
```

Create a function

This can be wrapped up into a function that takes the spdf variable created above

```
spdf <- SpatialPointsDataFrame(coords = data[,2:3], data = data.frame(data))</pre>
```

and returns a SpatialPixelsDataFrame object:

```
user.prod.accuracy <- function(spdf, Field.class = "Boolean_FS",
    RS.class = "Boolean_RS", bw = 0.15, grid=grid, family= binomial){
    class.list <- unique(spdf@data[,RS.class])[order(unique(spdf@data[,RS.class]))]
    # pass this into a loop
    for (i in 1:length(class.list) ){
        class <- class.list[i]
        # 1. Construct the variable pair
        # RS indicates the class
        rs.class <- (data$Boolean_RS == class) * 1
        # FS indicates the class
        fs.class <- (data$Boolean_FS == class) * 1
        # join together
        fsrs <- data.frame(cbind(fs.class,rs.class))</pre>
```

```
# convert to SPDF
  fsrs.spdf <- SpatialPointsDataFrame(coords = data[,2:3],</pre>
    data = data.frame(fsrs))
  # 2. GW User accuracy
  # define a bandwidth
  bw = 0.15
  # construct GW model
  gwr.mod <- ggwr(fs.class~rs.class, data = fsrs.spdf,</pre>
    adapt = bw,fit.points=grid, family= binomial)
  coefs <- data.frame(gwr.mod$SDF)[,2:3]</pre>
  coefs[,2] <- rowSums(coefs)</pre>
  alogit <- function(x)\{\exp(x)/(1+\exp(x))\}
  gwr.user <- alogit(coefs[,2])</pre>
  # 3. GW Producer accuracy
  gwr.mod <- ggwr(rs.class~fs.class, data = fsrs.spdf,</pre>
    adapt = bw,fit.points=grid, family= binomial)
  coefs <- data.frame(gwr.mod$SDF)[,2:3]</pre>
  coefs[,2] <- rowSums(coefs)</pre>
  gwr.producer <- alogit(coefs[,2])</pre>
  # 4. Add these to the data frame
  # define some variable names
  tit.user <- sprintf("%s-User", class)</pre>
  tit.producer <- sprintf("%s-Producer", class)</pre>
  df <- data.frame(gwr.user, gwr.producer)</pre>
  # name the df
  names(df) <- c(tit.user, tit.producer)</pre>
  # and combine
  if(i ==1) df.res <- df
  if(i > 1) df.res <- data.frame(df.res, df)</pre>
gw.spdf <-SpatialPixelsDataFrame(gwr.mod$SDF, data.frame(df.res))</pre>
return(gw.spdf)
```

And then this can be called

```
gwr.all.spdf <- user.prod.accuracy(spdf, Field.class = "Boolean_FS",
    RS.class = "Boolean_RS", bw = 0.15, grid=grid, family= binomial)</pre>
```

Or accepting the defaults:

```
gwr.all.spdf <- user.prod.accuracy(spdf)</pre>
```

And the contents examined again:

```
summary(gwr.all.spdf@data)
```

```

```

The elements of the gwr.all.spdf variable can be mapped using the function defined earlier:

```
par(mar = c(0,0,1,0))
gw.mapping(gwr.all.spdf, tit = names(gwr.all.spdf)[1])
```

Of course the parameters can be adjusted:

```
gw.mapping(gwr.all.spdf, index = 2, tit = names(gwr.all.spdf)[2])
gw.mapping(gwr.all.spdf, index = 5, tit = names(gwr.all.spdf)[5],
    cols = brewer.pal(6,'Spectral'))
# or write to a file
png(filename = "plot.png")
gw.mapping(gwr.all.spdf, index = 5, tit = names(gwr.all.spdf)[5],
    cols = brewer.pal(6,'YlOrRd'))
dev.off()
```

Or even put into a loop:

```
for (i in seq(2, 10, by = 2)) {
  gw.mapping(gwr.all.spdf, index = i, tit = names(gwr.all.spdf)[i])
}
```

And other shading schemes are available - see:

```
display.brewer.all()
```
